

When should we use throw and throws, try and catch?

If we are developing a method logic to execute by taking values from other programmer, in this method logic we must use throw and throws for throwing and reporting an exception if wrong values are passed.

If we want to just suppress exception and continues next lines of code execution or if we develop end-user interaction logic for reading input and displaying output, in this method we must use try, catch.

In simple terms we can say

- > in business logic development or in reusable logic development we must use throw and throws keywords
- > for just suppressing exception or in end-user interaction logic development we must use try and catch keywords
