

Types of exceptions:

2 types of exceptions

- 1) Checked exceptions
- 2) unchecked exceptions

When we throw an exception, if compiler checking this exception handling, if we do not handle this exception either by reporting or by catching if we get compile time error, we will call this exception as checked exception.

When we throw an exception, if compiler is not checking this exception handling, if we do not handle this exception either by reporting or by catching if we do not get compile time error, we will call this exception as unchecked exception.

When you find

- 1) serious/huge data lose
 - 2) when we are accessing outside resources (class file, files, DB, network connections)
- in this situation we must create an exception as checked exception

When you find

- 1) data lose will there, but we can ignore
- 2) not accessing outside resources

in this situation we must create an exception as unchecked exception

```
class Zoo {  
    void add(LivingThing lt) {  
        // ...  
    }  
}
```

```
if (lt instanceof D) {  
    // ...  
}
```
