

### What is a checked exception?

The classes Throwable, Exception and their direct sub classes are called checked exceptions.

The classes Error, RuntimeException and their direct sub classes are called as unchecked exception classes

### Why these exceptions are called as checked exceptions?

Because these exceptions' handling is **checked** by compiler and these exceptions are thrown by developer by **checking** one condition, these exceptions are called as checked exceptions. When we throw these exceptions, compiler will check whether these exceptions are handled or not either by using throws keyword or by using try/catch, if not handled it will throw error.

Checked exceptions are **mandatory** to handle, either by using throws keyword for reporting to this method caller or by using try/catch for catching this exception here in this same method, else we will get compile time error.

### When we must create an exception class as checked exception class means sub class of Exception?

If an exception class is representing external resources missing problems, for example file connection, data base connection or critical data loss problems, for example money deducted from account, we must create that exception class as checked exception class. So that compiler will force us to handle this exception, so that we will verify whether those resources are available or not and also we will add alternative code when failed.
