

Types of Exceptions

- 1) Error
- 2) RuntimeException
- 3) checked exceptions

Error	Exception
The exception those are sub classes of Error are called Error type exception. We will get those exceptions when there is problem in JVM memory level. Ex: NCDfE, NSME, NSFfE, OOME, SOfE, CFfE, LE, ... Error type exceptions represents JVM internal problems We donot catch Error type exceptions because no use of them we can not recover the situation. We must shutdown JVM and must solve the problem by doing some change either in code or at memory level.	The exception classes those are derived from Excetion are called Exception type exceptions. We will get Exception type exceptions when there is problem in Java code level/API level Ex: CNFE, NSME, NSFfE, AE, CCE, NPE, NfE, AIOOBfE, NASE, ASE, IOE, FNfE, SQLfE, etc... Exception type exceptions represents the Java code level problems occurred because wrong inputs or because of wrong logic. We must catch Exception type exception to recover the problem termination and terminate program execution smootly/normally.

Exception type exception are again devided into two types

- 1) RuntimeException (class)
- 2) checked exceptions (not class, just concept name)

RuntimeException	checked exceptions
The exception classes those are sub classes of RuntimeException are called RuntimeException type classes. These exception are raised because either wrong values or becasue of wrong logic. These exceptions are thrown either by JVM or by programmer by checked some condtion. These exception are optoinal to handle, no need to report or no need to catch.	The exception classes are direct sub classes Throwable or Exception are called checked exceptions. These exception classes are called checked exceptions, because of two reasons, 1) These exceptions are only thrown by programmer by checked one condition 2) These exceptions handing is checked by compiler, if we do not handle, compiler will throw an error These exceptions are mandatory to handle either by reporting or by catching
